

AI Business Operations Agent

Complete Workflow

Purpose: The AI Business Operations Agent acts like an intelligent digital employee. It receives business requests and information, understands the request, identifies the correct staff member, creates or updates the required task, and tracks the work until completion.

1. Customer Request / Business Query

The workflow starts when a customer or business user submits a request. The request can be related to an invoice, payment reminder, customer inquiry, appointment, document, phone call, email, or message.

2. Request Goes to the AI Agent

The request is sent to the AI Agent. The agent reads the request and understands what the customer needs. It can also use existing customer, invoice, document, and task information from the system.

3. AI Agent Analyzes and Classifies the Request

The AI Agent identifies the request type, priority, customer details, required action, and the department or staff member responsible for handling it. If multiple requests are related, the agent can compare them and group or prioritize them before assigning the work.

4. Request Is Compared With Existing Work

Before creating a new task, the agent checks existing tasks and pending requests. This helps avoid duplicate work and allows related requests to be connected. For example, if a customer has already raised a payment issue, a new payment reminder request can be linked to the same customer and invoice.

5. Request Is Routed to the Correct Staff

After analysis, the AI Agent sends the task to the appropriate staff member or department. For example: payment issues go to Accounts, customer questions go to Customer Support, technical issues go to Technical Support, and operational requests go to the responsible operations staff.

6. Staff Performs the Work

The assigned staff member receives the task and performs the required action. The staff member can update the task status, add notes, upload documents, or provide the result.

7. Approval When Required

For sensitive actions such as sending an important email, SMS, payment reminder, or other external communication, the AI can prepare the action and place it in the Approval section. The authorized user reviews and approves it before execution.

8. Communication Is Sent Through the Correct Channel

Request Type	System Action
Email	Uses the existing Email Sender and SMTP configuration.

SMS / Message	Uses the Message Center and SMS sending workflow.
Phone / Call	Uses the existing Phone/Call functionality.

9. Result Is Updated

After the work is completed, the task status is updated. Typical statuses are Pending, In Progress, Waiting for Approval, Completed, or Failed.

10. Dispatched Logs and Tracking

Every communication or automated action is recorded in Dispatched Logs. The system stores the action, recipient, time, status, and result. This gives the business a clear history of what the AI and staff have done.

End-to-End Workflow

Customer Request → AI Agent → Understand & Classify → Compare With Existing Requests → Assign to Correct Staff → Staff Performs Work → Approval if Required → Email / SMS / Phone → Update Status → Dispatched Logs → Task Completed

Example

Customer: Bharath has a pending invoice amount of ₹5,000.

Step 1: The invoice information is available in the system.

Step 2: The AI Agent identifies that ₹5,000 is still pending.

Step 3: It creates a payment reminder task and routes it to the responsible staff.

Step 4: The AI prepares the reminder message.

Step 5: After approval, the message is sent through the configured communication channel.

Step 6: The result is recorded in Dispatched Logs and the task status is updated.

Key Benefit: The AI Agent does not simply answer requests. It understands the request, coordinates the work, routes it to the right person, supports communication, and keeps a complete record of the business operation.
